Overview

A proof-of-concept project

- Can a **tracking TPC** work for Belle in the future? (2030+ SuperKEKB luminosity upgrade)
- **Fine 3D segmentation** in principle is far more tolerant of high rates/high backgrounds

*This project: demonstrate **proof-of-concept** for a tracking TPC in Belle II. Use **LCTPC** as a starting point with **Belle II** simulation.*

Status

Working towards a white paper

- We are a small team of **Belle II** and **LCTPC** collaborators
- We have been working for ~4 months:
 - One masters thesis in progress
 - One PhD thesis portion in progress
 - Others contributing less formally
- Working towards a White Paper for summer 2021

- Can't put readout on FWD side (asymmetric collider-->PID detector in FWD region is beyond tracking volume)
- Inner tracking volume has strange shape, not appropriate for TPC
 - Abandon to expanded silicon

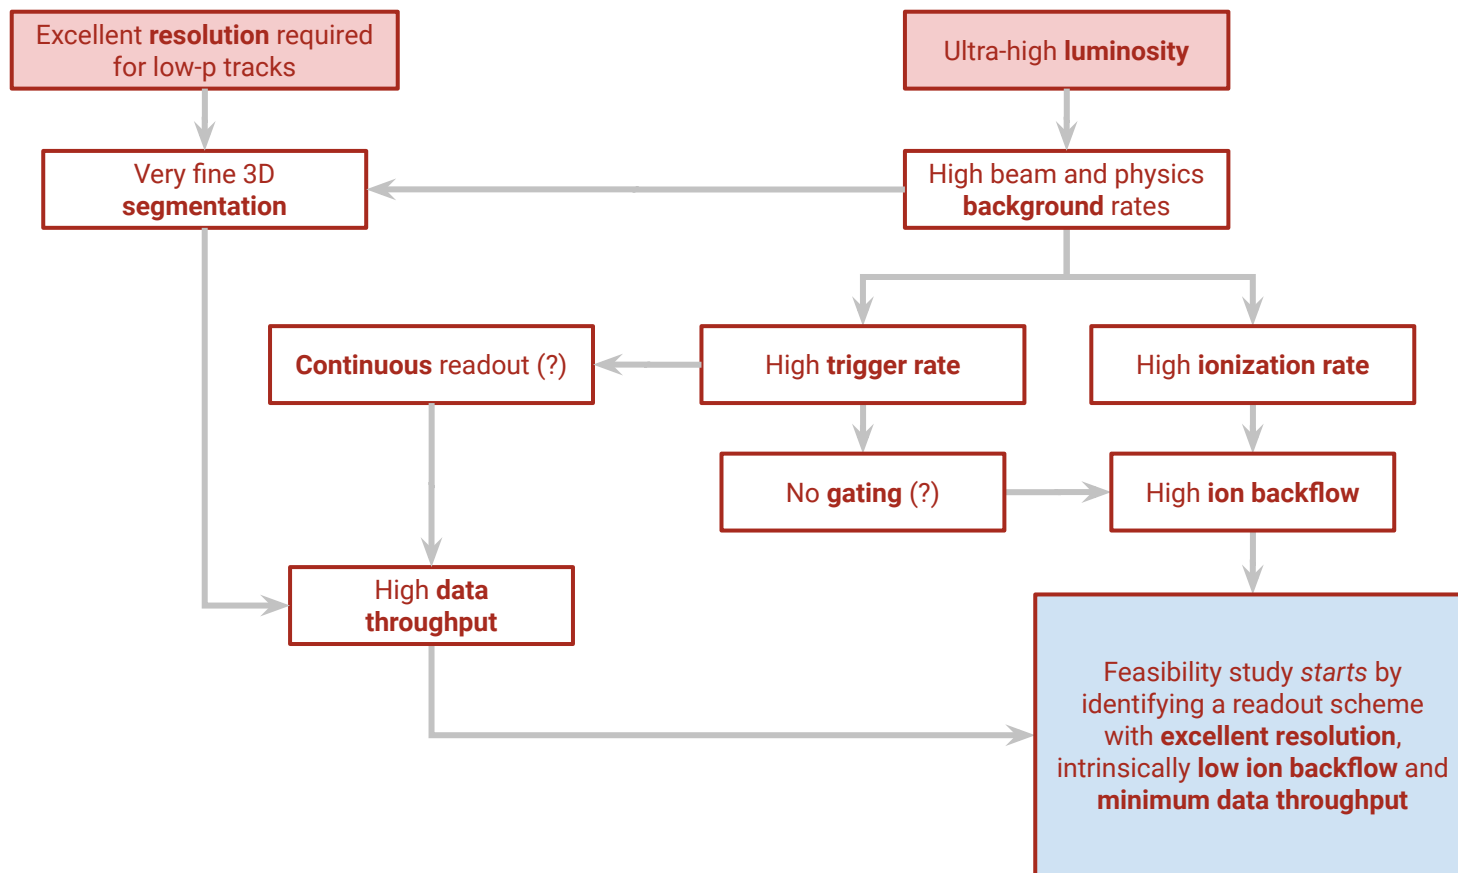

Primary technical concerns

“This won’t work at Belle because...”

- TPC can’t provide a **trigger**
- **Event rate is too high**
- No dE/dx for low- p_T tracks
- ...

Our first goal is to demonstrate **potential solutions** to these problems in simulation

(some) Readout considerations

GridPix: a starting point

Pixel chip with integrated MICROMEGAS

Excellent resolution:

- 50x50x pixels

Low throughput:

- **Single-electron** detection
- Can use **binary readout**

Low intrinsic ion backflow:

- (LCTPC): Ion backflow as low as **1 ion per primary electron**, with >90% efficiency

Simulation

Where we are right now

- Currently a combination of Belle 2 simulation and standalone code
- Currently implemented:
 - One electron \rightarrow one hit (approximating InGrid detector)
 - Pixel chip, binary readout ($50 \times 50 \times 50 \mu\text{m}^3$ voxels)
 - **T2K gas** with simulated **diffusion** and ionization properties
- Currently **not** implemented:
 - Field cage, drift field, field uniformity, etc.

Simulation demo: dE/dx

Simulation demo: micro-curlers (100 pions)

Early work
addressing the
technical concerns

Event pileup

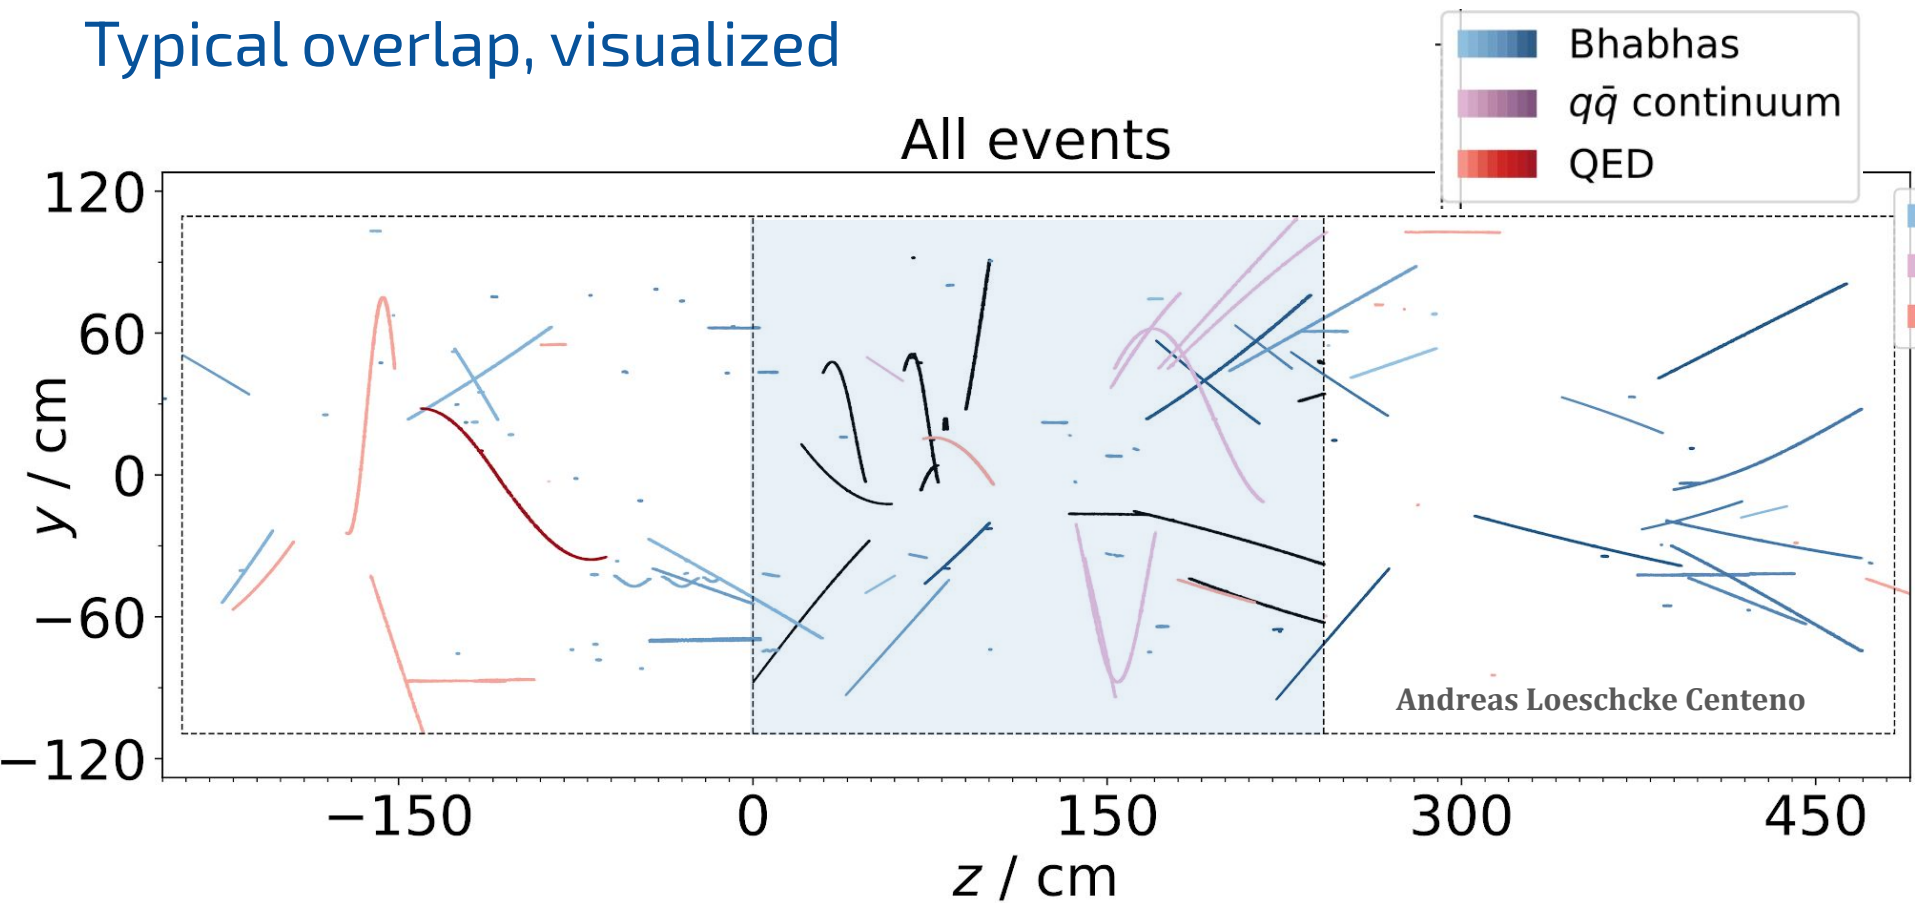

Per 30us drift volume

- *Full Belle II luminosity*
- Bhabha dominated (but these should be relatively easy to identify and remove)
- We have **many tools** (IP pointing, diffusion, etc.) to identify and remove overlaid physics
- Overall this isn't a problem... and furthermore shows that **gating may not be impossible** (depending on target luminosity)

Assuming triggered on an $Y(4S)$ event

Typical overlap, visualized

Background pileup

Now with **beam backgrounds**

- The hit rate/ionization rate is **dominated** by beam backgrounds...

Background pileup

Now with **beam backgrounds**

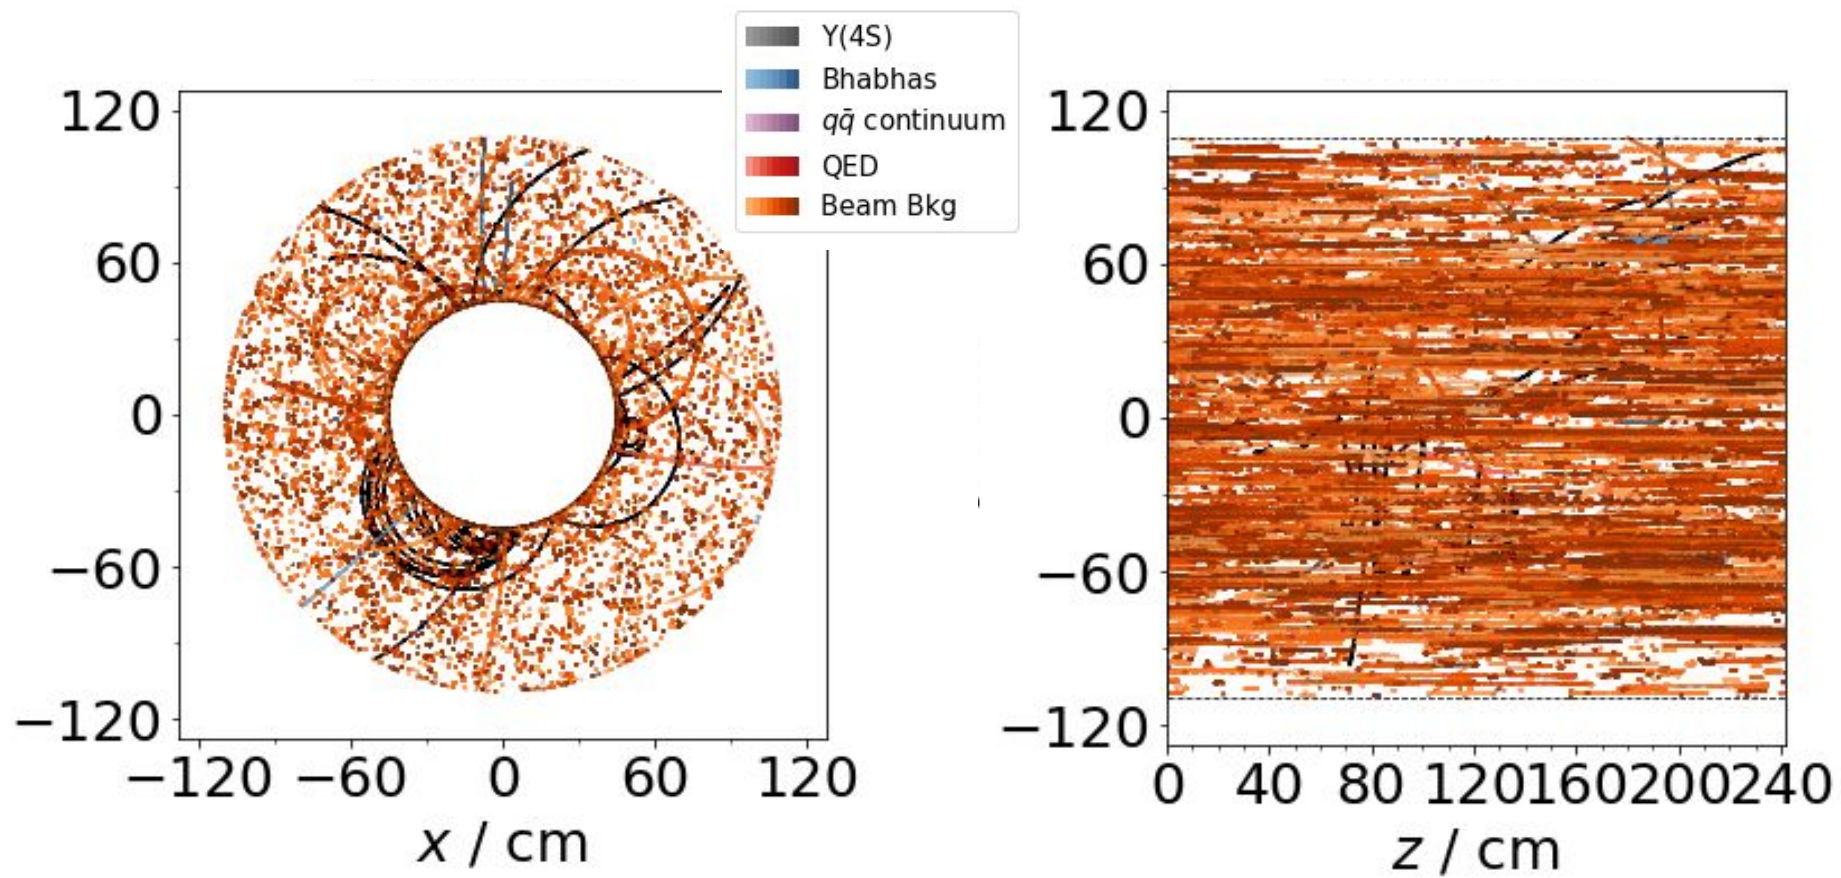

- The hit rate/ionization rate is **dominated** by beam backgrounds...
- These lead to **low-energy microcurlers**
 - Responsible for **huge majority of total ionization**
 - Evaluating multiple ways to suppress (from chip trigger masks and FPGA algorithms through tracking filters)
 - LCTPC has shown excellent rejection of these kinds of hits: we should too
 - ***But*** this will still lead to high **ion backflows**

Background rejection

The next steps

Evaluate **performance**

- Key tracking variable \mathbf{p}_T :
 - Dependence on amplification/readout choice?
 - Dependence on background rates?
 - Effect of ion backflow?
 - Effect of diffusion?
- Particle identification via dE/dx

The next steps

Evaluate **multiple TPC scenarios**

- Replace pixels with pads/strips, something else?
 - Cost
 - Unnecessary resolution (?)
- Ion backflow suppression:
 - GEM stack (low backflow, higher data throughput)
 - Partial or adaptive gating (?)
- Potential alternative gases (for v_d , ion mobility, etc.)

Our *goal* for the white paper is to evaluate several possible scenarios, at least one of which will (hopefully) meet Belle II+ tracking requirements
